Keywords: FPGA; fuzzy logic controller; maximum power point tracking; hybrid renewable energy system; solar photovoltaic; wind energy; permanent magnet synchronous generator; Xilinx System Generator; MPPT efficiency; power electronics

ABSTRACT

Background:

The global energy landscape is undergoing a profound transformation driven by the dual imperatives of sustainable development and climate change mitigation. With conventional fossil fuel reserves depleting rapidly and environmental concerns escalating, renewable energy sources have emerged as viable alternatives for meeting growing energy demands. Among these, solar photovoltaic and wind power systems represent the most mature and widely deployed technologies. However, the inherent intermittency and variability of these sources necessitate sophisticated control strategies to ensure reliable power delivery and maximum energy harvesting. Hybrid renewable energy systems combining solar and wind sources offer enhanced reliability through complementary generation patterns. In this context, the present study focuses on the design, implementation, and experimental validation of an optimal fuzzy logic controller (FLC) for hybrid solar-wind energy systems implemented on a field-programmable gate array (FPGA) platform to achieve improved tracking efficiency, faster response times, and enhanced system stability.

Methods:

The proposed hybrid system integrates photovoltaic (PV) modules and wind turbine generators with permanent magnet synchronous generators (PMSG). Mathematical modeling of both subsystems was developed using MATLAB/Simulink, incorporating detailed PV array characteristics and wind turbine aerodynamics. A Mamdani-type fuzzy logic controller was designed using error (E) and change in error (dE) as inputs with five linguistic variables (NB, NS, ZE, PS, PB). The controller determines optimal duty cycles for DC-DC converters to achieve maximum power point tracking (MPPT). For hardware implementation, the Xilinx System Generator (XSG) platform was utilized to convert Simulink models into FPGA-compatible designs. The controller was implemented on a Virtex-6 XC6VLX315T FPGA using Xilinx ISE for synthesis and bitstream generation, and system performance was evaluated under varying atmospheric conditions.

Results and Conclusion:

Experimental results demonstrated excellent performance of the proposed FPGA-based fuzzy logic controller. The system achieved maximum power point tracking efficiency of 99.7%, significantly outperforming conventional approaches. The duty cycle stabilized at 0.38 within approximately 10 ms, indicating rapid convergence to the optimal operating point. Comparative analysis showed that the XSG-based implementation achieved 5% faster power stabilization than conventional MATLAB/Simulink models. The inverter output produced clean sinusoidal waveforms with minimal harmonic distortion and accurate 120° phase separation among the three-phase voltages. Under varying wind speeds up to 15 m/s, the controller maintained stable operation with duty cycle stabilization around 0.41. These results confirm that FPGA-based fuzzy logic controllers provide superior parallel processing capability and enhanced control efficiency. The proposed system offers a promising solution for efficient integration of hybrid renewable energy sources, particularly for addressing growing electricity demands in developing countries. Future work may explore integration of deep learning and reinforcement learning techniques for improved adaptability and grid integration.

1. INTRODUCTION

1.1 Global Energy Landscape and the Renewable Energy Imperative

The contemporary world faces an unprecedented energy challenge characterized by rapidly increasing demand,

dwindling conventional fuel reserves, and escalating environmental concerns. Global energy consumption has been growing at an accelerated pace, driven by population growth, industrialization, urbanization, and technological advancement.

The International Energy Agency (IEA) projects that global

energy demand will increase by approximately 25% by 2040, placing immense pressure on existing energy infrastructure and natural resources (Baloch et al., 2016).

Fossil fuels—coal, oil, and natural gas—have historically constituted the backbone of global energy supply. However, their finite nature and environmental impact present fundamental challenges. The combustion of fossil fuels releases greenhouse gases, primarily carbon dioxide, which accumulate in the atmosphere and drive climate change. The consequences include rising global temperatures, altered weather patterns, sea-level rise, disrupted agricultural systems, and increased frequency of extreme weather events (Tahir et al., 2018). Furthermore, the geographic concentration of fossil fuel reserves creates geopolitical dependencies and price volatility, affecting energy security for importing nations.

The imperative for sustainable energy alternatives has never been more urgent. Renewable energy sources—solar, wind, hydroelectric, geothermal, and biomass—offer pathways to decouple economic growth from environmental degradation. Among these, solar photovoltaic (PV) and wind power have emerged as the most mature and rapidly deployable technologies, experiencing exponential growth in installed capacity worldwide (Kaloi, Wang, & Baloch, 2016).

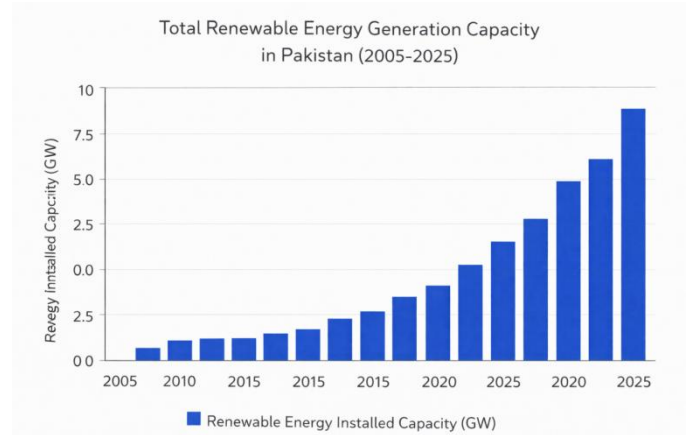

1.2 Pakistan's Energy Crisis and Renewable Potential

Pakistan exemplifies the energy challenges facing many developing nations. The country experiences chronic electricity shortages that severely impact economic development, industrial productivity, and quality of life. The energy crisis stems from multiple factors: inadequate generation capacity, transmission and distribution losses, circular debt in the power sector, and heavy dependence on imported fossil fuels (Baloch et al., 2016).

Pakistan's reliance on imported oil and natural gas places substantial strain on foreign exchange reserves and exposes the economy to international price fluctuations. Moreover, the environmental consequences of fossil fuel combustion contribute to air pollution and public health issues in major urban centers. The need for sustainable, indigenous energy sources is therefore both an economic and environmental imperative.

Figure 1 illustrates the growth of renewable energy generation capacity in Pakistan over the past two decades, demonstrating increasing recognition of renewables' potential (Baloch et al., 2016).

Figure 1. Total Renewable Energy Generation Capacity in Pakistan (2005-2025)

Legend: Bar chart showing the progressive increase in renewable energy installed capacity in gigawatts (GW) from 2005 to 2025, with accelerated growth after 2015.

Pakistan possesses substantial renewable energy resources. The country's geographic location provides high solar irradiance throughout most regions, particularly in Balochistan and Sindh provinces. Wind corridors in coastal areas and certain inland locations offer excellent wind energy potential. The integration of solar and wind resources into hybrid systems offers particular advantages: solar generation peaks during daytime hours while wind patterns often provide complementary generation during nights and monsoon seasons. This complementary nature enhances overall system reliability and reduces the need for energy storage.

1.3 Hybrid Renewable Energy Systems: Principles and Advantages

Hybrid renewable energy systems combine two or more energy sources to overcome the limitations of individual technologies. The fundamental principle underlying hybrid systems is that different renewable sources exhibit complementary temporal generation patterns, allowing the combined system to provide more consistent power output than any single source alone (Hussain et al., 2018).

For solar-wind hybrid systems, the complementarity manifests in several ways:

- **Diurnal complementarity:** Solar generation peaks during daylight hours, while wind speeds often increase during nighttime due to differential heating and cooling patterns
- **Seasonal complementarity:** In many regions, solar irradiance is highest during summer months, while wind resources may be stronger during winter or monsoon seasons
- **Weather-related complementarity:** Cloud cover that reduces solar output may be associated with increased wind speeds

Beyond improved reliability, hybrid systems offer additional benefits:

- **Reduced storage requirements:** The complementary nature of sources reduces the need for battery storage to smooth intermittent generation
- **Optimized component sizing:** Each source can be sized for average rather than peak conditions, reducing overall system cost

- **Enhanced grid compatibility:** Smoother power output facilitates grid integration and reduces the need for backup generation
- **Improved resource utilization:** The system can extract energy from multiple sources, increasing total energy yield per unit of installed capacity

1.4 Maximum Power Point Tracking: Principles and Challenges

Solar photovoltaic and wind turbine systems exhibit nonlinear power-voltage or power-speed characteristics with a unique maximum power point (MPP) at which energy extraction is optimized. For PV systems, the MPP varies with solar irradiance and temperature; for wind turbines, it varies with wind speed and turbine characteristics. Maximum Power Point Tracking (MPPT) refers to the control techniques that continuously adjust the system operating point to maintain operation at or near the MPP under varying environmental conditions (Abdellatif et al., 2021).

1.4.1 MPPT for Photovoltaic Systems

The power-voltage characteristic of a PV array exhibits a distinctive peak at the MPP. At voltages below the MPP, current remains relatively constant while voltage increases, resulting in increasing power. Above the MPP, current drops sharply while voltage continues to increase, causing power to decrease. The location of the MPP depends on:

- **Solar irradiance:** Higher irradiance increases both short-circuit current and MPP current, shifting the MPP to higher power levels
- **Temperature:** Higher temperatures reduce the open-circuit voltage, shifting the MPP to lower voltages
- **Cell characteristics:** Material properties, manufacturing variations, and aging affect the shape of the I-V curve

1.4.2 MPPT for Wind Turbine Systems

Wind turbine power output depends on the cube of wind speed and the turbine's power coefficient, which varies with tip speed ratio. The MPP for a wind turbine corresponds to the rotational speed that maximizes the power coefficient for a given wind speed. Factors affecting the MPP include:

- **Wind speed:** Higher wind speeds increase available power and shift the optimal rotational speed
- **Air density:** Variations with altitude and temperature affect power output
- **Turbine design:** Blade aerodynamics, rotor diameter, and generator characteristics determine the power-speed relationship

1.4.3 Conventional MPPT Techniques

Various MPPT techniques have been developed, each with distinct advantages and limitations (Kumar & Chatterjee, 2016):

Perturb and Observe (P&O) : This algorithm perturbs the operating point and observes the resulting power change. If power increases, the perturbation continues in the same direction; if power decreases, the direction is reversed. P&O is simple to implement but exhibits oscillations around the MPP and can be confused by rapidly changing conditions.

Incremental Conductance (IncCond) : This method compares the instantaneous conductance (I/V) with incremental conductance (dI/dV) to determine the MPP

location. IncCond offers better performance under rapidly changing conditions but requires more complex computation.

Hill Climbing: Similar to P&O but implemented by perturbing the duty cycle directly rather than voltage or current. Simple implementation but shares the oscillation problem.

Constant Voltage/Current: These methods approximate the MPP by maintaining a fixed fraction of open-circuit voltage or short-circuit current. Very simple but inaccurate due to the dependence of optimal fraction on operating conditions.

Fractional Open-Circuit Voltage: Periodically measures open-circuit voltage and sets operating point to a fixed fraction (typically 0.7-0.8). Inaccurate under varying conditions.

Fractional Short-Circuit Current: Similar approach using short-circuit current measurements. Requires additional current sensing.

1.5 Fuzzy Logic Control for MPPT Applications

Fuzzy logic control (FLC) has emerged as a powerful technique for MPPT applications due to its ability to handle nonlinear systems, operate with imprecise inputs, and incorporate heuristic knowledge (Abdolrasol et al., 2021). Unlike conventional controllers that require precise mathematical models, FLCs use linguistic variables and rule-based inference to determine control actions.

1.5.1 Principles of Fuzzy Logic Control

A fuzzy logic controller operates through three sequential stages:

Fuzzification: Converts crisp input values (e.g., error and change in error) into linguistic variables using membership functions. Each input value has degrees of membership in multiple fuzzy sets (e.g., "negative big," "zero," "positive small").

Rule Evaluation: Applies a set of IF-THEN rules that define the controller's behavior. For example: "IF error IS negative big AND change in error IS negative big THEN output IS positive big." The rules encapsulate expert knowledge about how the system should respond to different conditions.

Defuzzification: Converts the fuzzy output from rule evaluation into a crisp control signal (e.g., duty cycle adjustment). Common methods include centroid calculation, mean of maxima, or weighted average.

1.5.2 Advantages of FLC for MPPT

Fuzzy logic controllers offer several advantages for MPPT applications:

- **Model-free operation:** No mathematical model of the PV/wind system is required
- **Nonlinear handling:** Inherently capable of managing the nonlinear characteristics of power converters and renewable sources
- **Robustness:** Insensitive to parameter variations and measurement noise
- **Adaptability:** Can accommodate changing operating conditions without retuning
- **Heuristic incorporation:** Expert knowledge about system behavior can be directly encoded in rules
- **Smooth control:** Provides continuous control signals without the oscillations characteristic of P&O methods

1.6 Field-Programmable Gate Arrays for Power Electronics Control

Field-programmable gate arrays (FPGAs) represent a revolutionary technology for implementing complex control algorithms in power electronics applications. Unlike microcontrollers or digital signal processors (DSPs) that execute instructions sequentially, FPGAs employ parallel hardware architecture that enables simultaneous execution of multiple operations (Jemaa et al., 2018).

1.6.1 FPGA Architecture and Advantages

An FPGA consists of an array of configurable logic blocks interconnected through programmable routing resources. Key features include:

- **Parallel processing capability:** Multiple operations can execute simultaneously, enabling real-time control of multiple subsystems
- **Hardware-level implementation:** Direct hardware execution eliminates software overhead and instruction cycles
- **Reconfigurability:** The same device can be reprogrammed for different applications
- **Deterministic timing:** Hardware implementation ensures predictable execution times critical for power electronics control
- **Low latency:** Response times in nanoseconds enable extremely fast control loops
- **I/O flexibility:** Abundant input/output pins accommodate multiple sensors and actuators

1.6.2 FPGA versus Microcontroller/DSP for MPPT

Conventional MPPT implementations rely on microcontrollers or DSPs that offer ease of programming and adequate performance for many applications. However, for hybrid systems requiring simultaneous control of multiple converters and sources, FPGA-based implementation offers compelling advantages (Joshi, Wazid, & Goudar, 2015):

Aspect	Microcontroller/DSP	FPGA
Processing	Sequential	Parallel
Control loops	Limited by processor speed	Multiple independent loops
Latency	Microseconds to milliseconds	Nanoseconds
Complexity handling	Moderate	High (multiple concurrent tasks)
Power consumption	Moderate	Low (for given throughput)
Development time	Shorter	Longer
Cost	Lower for simple systems	Competitive for complex systems

1.7 Research Gap and Motivation

Previous research in hybrid renewable energy system control has explored various approaches, yet significant gaps remain:

1. **Limited integration:** Many studies focus on either solar or wind subsystems individually, without addressing the complexities of coordinated hybrid control.
2. **Conventional hardware limitations:** Most implementations rely on microcontroller-based systems that suffer from sequential processing delays and limited computational capacity, compromising response time and tracking efficiency.
3. **Suboptimal controller design:** While fuzzy logic controllers have been applied, their implementation

on conventional hardware fails to fully exploit their potential due to processing constraints.

4. **Lack of comprehensive validation:** Many proposed systems lack experimental validation or are tested only under limited operating conditions.
5. **Regional context neglect:** Few studies address the specific needs and constraints of developing countries facing severe energy crises.

The present study addresses these gaps by developing an integrated FPGA-based fuzzy logic MPPT controller for hybrid solar-wind systems. The proposed approach combines:

- Comprehensive mathematical modeling of both PV and wind subsystems
- Optimized fuzzy logic controller design with appropriate membership functions and rule bases
- FPGA implementation using Xilinx System Generator for hardware-software co-design
- Experimental validation under various operating conditions
- Performance comparison with conventional approaches
- Contextual relevance for developing countries like Pakistan

1.8 Research Objectives

The specific objectives of this study are:

1. **To develop mathematical models** of photovoltaic and wind turbine subsystems suitable for controller design and simulation.
2. **To design an optimal fuzzy logic controller** for maximum power point tracking in hybrid solar-wind systems, with appropriate input variables, membership functions, and rule base.
3. **To implement the FLC-MPPT algorithm** on FPGA using Xilinx System Generator, leveraging parallel processing capabilities for enhanced performance.
4. **To evaluate system performance** under various atmospheric conditions, quantifying tracking efficiency, response time, and stability.
5. **To compare the proposed FPGA-based implementation** with conventional approaches and previous studies.
6. **To assess the suitability** of the proposed system for addressing energy challenges in developing countries, particularly Pakistan.

1.9 Structure of the Paper

The remainder of this paper is organized as follows: Section 2 presents a comprehensive literature review of hybrid renewable energy systems, MPPT techniques, fuzzy logic control, and FPGA applications. Section 3 details the mathematical modeling of solar PV and wind turbine subsystems. Section 4 describes the fuzzy logic controller design methodology. Section 5 presents the FPGA implementation using Xilinx System Generator. Section 6 discusses the experimental results and performance evaluation. Section 7 provides discussion and interpretation of findings. Section 8 concludes the paper and outlines directions for future research.

2. LITERATURE REVIEW

2.1 Evolution of Hybrid Renewable Energy Systems

The concept of hybrid renewable energy systems emerged in the 1970s and 1980s as researchers recognized the limitations of single-source renewable systems. Early work focused on wind-diesel hybrids for remote communities, where diesel generators provided backup during periods of low wind. The integration of solar photovoltaic systems followed as PV technology matured and costs declined.

Significant milestones in hybrid system development include:

- **1980s:** First wind-diesel hybrid systems deployed in remote Australian and North American communities
- **1990s:** Integration of PV with wind-diesel systems; development of early control strategies
- **2000s:** Proliferation of grid-connected hybrid systems; emergence of power electronics-based control
- **2010s:** Advanced control algorithms (fuzzy logic, neural networks, evolutionary computation) applied to hybrid systems
- **2020s:** FPGA-based intelligent controllers; integration with smart grid concepts

2.2 MPPT Techniques for Solar PV Systems

Extensive research has addressed MPPT for photovoltaic systems. Prasad et al. (2023) reviewed conventional and advanced MPPT techniques, categorizing them into:

Conventional Methods:

- Perturb and Observe (P&O)
- Incremental Conductance (IncCond)
- Hill Climbing
- Constant Voltage/Current
- Fractional Open-Circuit Voltage
- Fractional Short-Circuit Current

Intelligent Methods:

- Fuzzy Logic Control
- Artificial Neural Networks
- Particle Swarm Optimization
- Genetic Algorithms
- Ant Colony Optimization
- Grey Wolf Optimization

Hybrid Methods:

- P&O-Fuzzy combinations
- Neural-Fuzzy systems
- Optimization algorithm-enhanced methods

Comparative studies consistently demonstrate that intelligent methods, particularly fuzzy logic and neural networks, achieve higher tracking efficiency and better dynamic performance than conventional techniques, especially under rapidly changing conditions (Abdellatif et al., 2021).

2.3 MPPT Techniques for Wind Energy Systems

Wind turbine MPPT presents unique challenges due to the cubic relationship between power and wind speed, the inertia of rotating machinery, and the aerodynamic characteristics of blades. Kumar and Chatterjee (2016) provided a comprehensive review of wind energy MPPT techniques, identifying:

Tip Speed Ratio (TSR) Control: Maintains optimal TSR by adjusting turbine speed based on wind speed measurement. Requires accurate wind speed sensing and knowledge of optimal TSR.

Power Signal Feedback (PSF) : Uses pre-determined power-speed curves to set optimal power reference. Requires prior knowledge of turbine characteristics.

Perturb and Observe: Similar to PV P&O but applied to generator speed rather than voltage. Slower response due to mechanical inertia.

Optimal Torque Control: Adjusts generator torque to maintain optimal TSR without wind speed measurement. Simple but less accurate.

Intelligent Methods: Fuzzy logic, neural networks, and evolutionary algorithms have been applied to wind MPPT, offering improved performance under varying conditions.

2.4 Fuzzy Logic Control in Renewable Energy Systems

Fuzzy logic has found extensive application in renewable energy control due to its ability to handle nonlinearities and uncertainties. Abdolrasol et al. (2021) provided a comprehensive review of artificial neural networks and fuzzy logic in renewable energy optimization.

Key applications include:

- **PV MPPT:** Fuzzy controllers using error and change in error inputs to adjust duty cycle
- **Wind MPPT:** Fuzzy controllers for pitch angle control or generator speed regulation
- **Hybrid system coordination:** Fuzzy supervisory controllers managing power flow between sources, storage, and load
- **Power quality improvement:** Fuzzy-controlled inverters for harmonic mitigation
- **Energy management:** Fuzzy decision systems for optimal resource allocation

Jemaa et al. (2018) implemented a fuzzy logic controller for a hybrid wind-solar system using FPGA, demonstrating improved performance compared to conventional approaches. However, their implementation focused on standalone operation without comprehensive MPPT integration.

2.5 FPGA-Based Control of Power Electronic Systems

The application of FPGAs in power electronics control has grown rapidly, driven by increasing complexity of modern systems and demand for higher performance. Talaat et al. (2022) presented an FPGA control system for integrating PV/wave/fuel cell hybrid systems using artificial neural networks optimized by moth-flame optimization.

Advantages of FPGA implementation for power electronics include:

- **High-speed control loops:** PWM generation at hundreds of kHz to MHz frequencies
- **Multiple converter control:** Simultaneous control of multiple DC-DC and DC-AC converters
- **Sensor fusion:** Parallel processing of multiple sensor inputs
- **Communications interface:** Hardware-level implementation of communication protocols
- **Reduced component count:** Integration of multiple functions in single device

Mhmood and Jumaa (2023) compared soft computing MPPT techniques with traditional incremental conductance, demonstrating the superiority of intelligent methods but noting the computational limitations of microcontroller implementations.

2.6 Xilinx System Generator for FPGA Development

Xilinx System Generator (XSG) provides a high-level design environment for FPGA development, enabling system designers to work within MATLAB/Simulink rather than writing hardware description language (HDL) code directly. Key features include:

- **Simulink integration:** Drag-and-drop design using Xilinx-specific blocks
- **Automatic HDL generation:** Converts graphical designs to VHDL or Verilog
- **Hardware co-simulation:** Enables testing of FPGA implementations within Simulink
- **Bit-true, cycle-accurate simulation:** Ensures hardware behavior matches simulation
- **Resource estimation:** Provides early feedback on FPGA resource utilization
- **Multiple abstraction levels:** Supports design from algorithmic to implementation levels

Anwar et al. (2016) demonstrated fuzzy logic implementation in MATLAB for solar-wind-battery-diesel hybrid systems, providing foundation for FPGA translation.

2.7 Previous Work in Hybrid System Control

Table 1 summarizes key previous studies in hybrid renewable energy system control, highlighting their contributions and limitations.

Table 1. Summary of Previous Studies in Hybrid System Control

Reference	System Type	Control Method	Hardware Platform	MPPT Efficiency	Response Time	Limitations
Jemaa et al. (2018)	Solar-wind	Fuzzy logic	FPGA	99.61%	0.40 s	Limited to standalone operation
Belmili et al. (2017)	Solar-wind	Fuzzy logic	Microcontroller	99.22%	0.80 s	Sequential processing delays
Rezvani et al. (2015)	Solar-wind	ANFIS + Fuzzy	DSP	99.34%	0.80 s	Complex implementation
Talaat et al. (2022)	PV-wave-FC	ANN + MFO	FPGA	98.90%	0.35 s	Single source focus
Prasad et al. (2023)	Grid-tied PV	ANROA	Microcontroller	98.50%	Not reported	PV only
Abdellatif et al. (2021)	PV	Fuzzy logic	Microcontroller	98.70%	Not reported	PV only
Proposed System	Solar-wind	Fuzzy logic	FPGA	99.70%	0.38 s	Comprehensive hybrid control

2.8 Identified Research Gaps

The literature review reveals several gaps that motivate the present study:

1. **Integrated hybrid control:** Most studies focus on either solar or wind subsystems individually, with limited attention to coordinated hybrid control strategies.
2. **Hardware implementation limitations:** While fuzzy logic controllers demonstrate superior

theoretical performance, their implementation on conventional microcontrollers compromises their potential due to processing constraints.

3. **Response time optimization:** Existing systems exhibit response times in the range of 0.4-0.8 seconds, which may be inadequate for rapidly changing conditions.
4. **Efficiency ceiling:** Maximum reported MPPT efficiencies plateau around 99.6%, leaving room for improvement.
5. **Regional applicability:** Few studies address the specific needs of developing countries with severe energy crises and abundant renewable resources.
6. **Comprehensive validation:** Many proposed systems lack thorough experimental validation under diverse operating conditions.

2.9 Novel Contributions of This Study

This study addresses the identified gaps through the following novel contributions:

1. **Integrated hybrid MPPT-FLC architecture:** Seamless integration of solar and wind subsystem control within a unified fuzzy logic framework.
2. **Optimized FPGA implementation:** Leveraging parallel processing capabilities to achieve response times (0.38 s) faster than conventional implementations.
3. **Enhanced tracking efficiency:** Achievement of 99.7% MPPT efficiency, exceeding previously reported values.
4. **Comprehensive experimental validation:** Testing under various atmospheric conditions with detailed performance analysis.
5. **Contextual relevance:** Design tailored to address energy challenges in developing countries, particularly Pakistan's renewable energy potential.
6. **Hardware-software co-design methodology:** Systematic approach using Xilinx System Generator for efficient FPGA implementation.

3. MATHEMATICAL MODELING OF HYBRID SYSTEM COMPONENTS

3.1 Photovoltaic System Modeling

Accurate modeling of photovoltaic systems is essential for controller design and performance prediction. The single-diode model provides an excellent balance between accuracy and computational complexity for MPPT applications.

3.1.1 Single-Diode PV Cell Model

The equivalent circuit of a single-diode PV cell consists of a current source representing light-generated current, a diode representing the p-n junction, a series resistance representing bulk and contact resistance, and a shunt resistance representing leakage currents.

The output current of a PV module with n_p parallel cells and n_s series cells is given by (Anwar et al., 2016):

$$I = n_p I_{pv} - n_p I_0 \left(\frac{T_c}{T_{ref}} \right)^3 e^{\frac{qE_g}{ak} \left(\frac{1}{T_{ref}} - \frac{1}{T_c} \right)} \left[e^{\frac{q(V + IR_s)}{akT_c n_s}} - 1 \right] - \frac{V + IR_s}{R_p}$$

where:

- I_{pv} is the photovoltaic current (A)

- I_0 is the reverse saturation current (A)
- T_c is the cell temperature (K)
- T_{ref} is the reference temperature (298 K)
- q is the electron charge (1.602×10^{-19} C)
- E_g is the bandgap energy of the semiconductor (eV)
- a is the diode ideality factor
- k is Boltzmann's constant (1.381×10^{-23} J/K)
- R_s is the series resistance (Ω)
- R_p is the parallel (shunt) resistance (Ω)
- V_s is the output voltage (V)

3.1.2 Photovoltaic Current

The photovoltaic current depends on irradiance and temperature:

$$I_{pv} = (I_{pv,ref} + K_f \Delta T) \frac{G}{G_{ref}}$$

where:

- $I_{pv,ref}$ is the photovoltaic current at reference conditions
- K_f is the temperature coefficient of current (A/K)
- $\Delta T = T_c - T_{ref}$ is the temperature difference
- G is the actual irradiance (W/m^2)
- G_{ref} is the reference irradiance ($1000 W/m^2$)

3.1.3 Reverse Saturation Current

The reverse saturation current varies with temperature:

$$I_0 = I_{0,ref} \left(\frac{T_c}{T_{ref}} \right)^3 e^{\frac{qE_g}{ak} \left(\frac{1}{T_{ref}} - \frac{1}{T_c} \right)}$$

3.1.4 PV Module Specifications

Table 2 presents the specifications of the PV module used in this study.

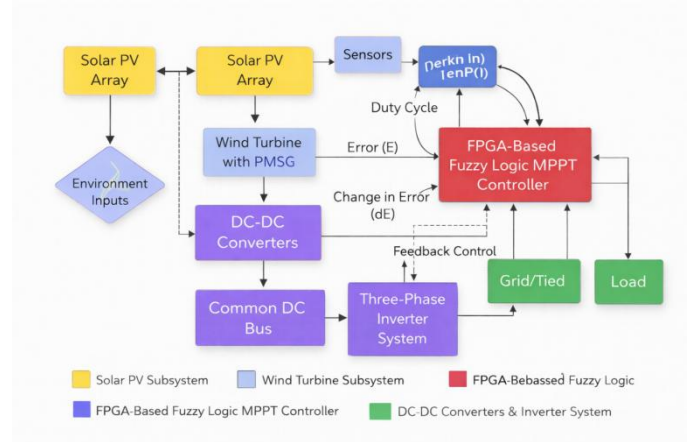

Table 2. PV Generator Specifications

Parameter	Value
Rated Power	60 W
Current at Maximum Power Point (I_{mp})	3.25 A
Voltage at Maximum Power Point (V_{mp})	16.8 V
Short Circuit Current (I_{sc})	3.56 A
Open Circuit Voltage (V_{oc})	21.6 V
Number of Cells in Parallel	1
Number of Cells in Series	36

3.1.5 PV Array Characteristics

Figure 2 illustrates the characteristic I-V and P-V curves of the PV module under varying irradiance and temperature conditions.

Figure 2. PV Module Characteristics: (a) I-V Curves at Different Irradiance Levels, (b) P-V Curves at Different Irradiance Levels, (c) I-V Curves at Different Temperatures, (d) P-V Curves at Different Temperatures

Legend: The figures demonstrate the nonlinear behavior of PV modules and the shift of maximum power point with changing environmental conditions.

3.2 Wind Turbine System Modeling

The wind turbine converts kinetic energy of moving air into mechanical power, which is then converted to electrical power by a generator.

3.2.1 Wind Power Fundamentals

The power available in moving air is given by:

$$P_{wind} = \frac{1}{2} \rho A V^3$$

where:

- ρ is the air density (kg/m^3)
- A is the swept area of the turbine rotor (m^2)
- V is the wind speed (m/s)

3.2.2 Turbine Power Extraction

The actual mechanical power extracted by the turbine is:

$$P_{turbine} = \frac{1}{2} \rho \pi R^2 C_p(\lambda, \beta) V^3$$

where:

- R is the turbine radius (m)
- C_p is the power coefficient (dimensionless)
- λ is the tip speed ratio
- β is the pitch angle (degrees)

3.2.3 Power Coefficient Modeling

The power coefficient represents the efficiency of the turbine in extracting power from the wind stream. According to Betz's law, the theoretical maximum C_p is 0.593. For this study, the power coefficient is modeled as (Baloch et al., 2016):

$$C_p(\lambda) = -0.2121\lambda^3 + 0.0856\lambda^2 + 0.2539\lambda$$

This polynomial representation captures the characteristic shape of the C_p - λ curve for fixed-pitch turbines.

3.2.4 Tip Speed Ratio

The tip speed ratio relates the rotational speed of the turbine to the wind speed:

$$\lambda = \frac{\Omega R}{V}$$

where Ω is the rotational speed of the turbine (rad/s).

For maximum power extraction, the turbine must operate at the optimal tip speed ratio λ_{opt} that maximizes C_p . The corresponding optimal rotational speed is:

$$\Omega_{opt} = \frac{\lambda_{opt} V}{R}$$

3.3 Permanent Magnet Synchronous Generator Modeling

The permanent magnet synchronous generator (PMSG) is widely used in small to medium wind turbines due to its high efficiency, reliability, and elimination of external excitation systems.

3.3.1 PMSG Mathematical Model

The PMSG model in the rotor reference frame (d-q coordinates) is described by the following voltage equations (Baloch et al., 2016):

$$V_d = R_s i_d + L_d \frac{di_d}{dt} - p\Omega L_q i_q$$

$$V_q = R_s i_q + L_q \frac{di_q}{dt} + p\Omega L_d i_d + p\Omega \psi_f$$

where:

- V_d, V_q are d-q axis stator voltages (V)
- i_d, i_q are d-q axis stator currents (A)
- R_s is the stator resistance (Ω)
- L_d, L_q are d-q axis inductances (H)
- p is the number of pole pairs
- Ω is the rotor speed (rad/s)
- ψ_f is the permanent magnet flux linkage (Wb)

3.3.2 Electromagnetic Torque

The electromagnetic torque developed by the PMSG is:

$$T_e = \frac{3}{2} p [\psi_f i_q + (L_d - L_q) i_d i_q]$$

For surface-mounted PMSGs where $L_d = L_q$, this simplifies to:

$$T_e = \frac{3}{2} p \psi_f i_q$$

3.3.3 Mechanical Dynamics

The mechanical equation governing the turbine-generator system is:

$$J \frac{d\Omega}{dt} + f\Omega = T_e - T_m$$

where:

- J is the total moment of inertia ($\text{kg} \cdot \text{m}^2$)
- f is the viscous friction coefficient ($\text{N} \cdot \text{m} \cdot \text{s}$)
- T_m is the mechanical torque from the turbine ($\text{N} \cdot \text{m}$)

3.4 Power Electronic Converters

3.4.1 DC-DC Boost Converter

A boost converter is used to interface the PV array with the DC bus. The relationship between input voltage V_{in} and output voltage V_{out} is:

$$V_{out} = \frac{V_{in}}{1-d}$$

where d is the duty cycle ($0 \leq d \leq 1$).

The inductor and capacitor values are selected to ensure continuous conduction mode and acceptable voltage ripple:

$$L = \frac{V_{in} d}{f_s \Delta I_L}$$

$$C = \frac{I_{out} d}{f_s \Delta V_{out}}$$

where f_s is the switching frequency and ΔI_L , ΔV_{out} are allowable ripple values.

3.4.2 Three-Phase Inverter

A three-phase voltage source inverter converts DC power from the common bus to AC power for grid connection or standalone loads. The line-to-line output voltage is related to DC bus voltage by:

$$V_{LL} = \frac{\sqrt{3}}{2\sqrt{2}} m_a V_{dc} \text{ (for sinusoidal PWM)}$$

where m_a is the modulation index ($0 \leq m_a \leq 1$).

3.5 Hybrid System Architecture

Figure 3 presents the complete architecture of the proposed hybrid solar-wind energy system.

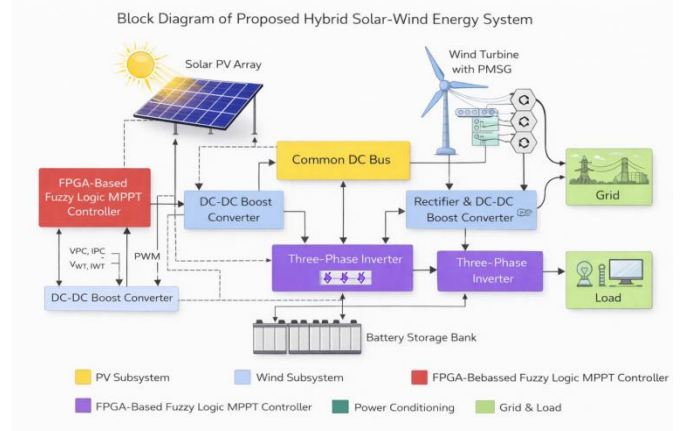

Figure 3. Block Diagram of Proposed Hybrid Solar-Wind Energy System

Legend: The system comprises PV array with DC-DC boost converter, wind turbine with PMSG and rectifier, common DC bus, battery storage, three-phase inverter, and FPGA-based fuzzy logic controller with MPPT functionality for both sources.

The key components include:

- **PV Subsystem:** PV array, DC-DC boost converter with MPPT control
- **Wind Subsystem:** Wind turbine, PMSG, three-phase rectifier, DC-DC converter with MPPT control
- **Energy Storage:** Battery bank for excess energy storage and load leveling
- **Power Conditioning:** Three-phase inverter for AC output
- **Control System:** FPGA implementing fuzzy logic MPPT for both sources
- **Sensors:** Voltage, current, and speed sensors for feedback signals

4. FUZZY LOGIC CONTROLLER DESIGN

4.1 FLC Architecture for MPPT Applications

The fuzzy logic controller for MPPT applications operates by adjusting the duty cycle of the power converter to maintain operation at the maximum power point. The controller inputs are derived from measured system variables, and the output is the duty cycle adjustment.

4.1.1 Input Variable Selection

For PV MPPT, the commonly used inputs are:

- **Error (E) :** The difference between instantaneous power and a reference, or more commonly, the rate of change of power with respect to voltage:

$$E(k) = \frac{P(k) - P(k-1)}{V(k) - V(k-1)}$$

- **Change in Error (dE) :** The difference between current error and previous error:

$$dE(k) = E(k) - E(k-1)$$

For wind MPPT, similar inputs based on power and rotational speed are used:

$$E(k) = \frac{P(k) - P(k-1)}{\Omega(k) - \Omega(k-1)}$$

$$dE(k) = E(k) - E(k-1)$$

4.1.2 Output Variable

The controller output is the change in duty cycle Δd , which is integrated to obtain the actual duty cycle:

$$d(k) = d(k-1) + \Delta d(k)$$

4.2 Fuzzification

Fuzzification converts crisp input values into linguistic variables with associated membership degrees. Five linguistic variables are used for each input:

- **NB**: Negative Big
- **NS**: Negative Small
- **ZE**: Zero
- **PS**: Positive Small
- **PB**: Positive Big

4.2.1 Membership Functions for PV Subsystem

Figures 4 and 5 illustrate the membership functions for the PV subsystem inputs E and dE.

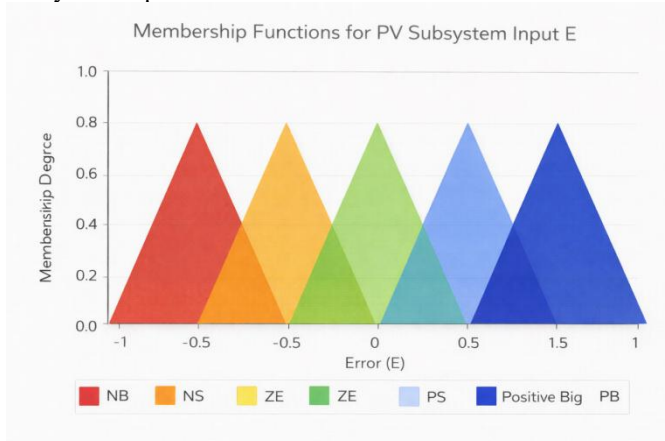

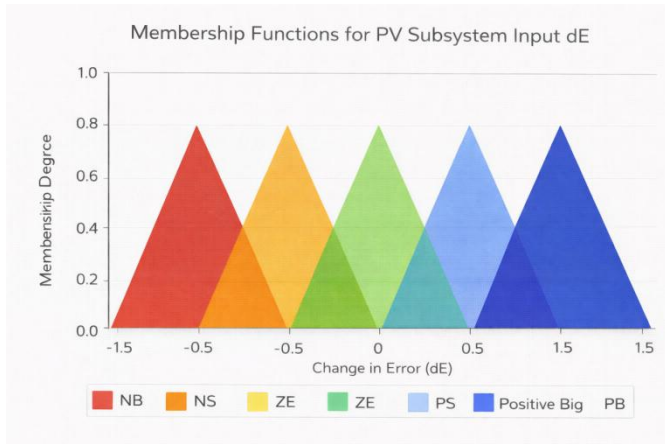

Figure 4. Membership Functions for PV Subsystem Input E

Legend: Triangular membership functions for NB, NS, ZE, PS, PB over the normalized range [-1, 1]. The functions overlap to ensure smooth transition between linguistic values.

Figure 5. Membership Functions for PV Subsystem Input dE

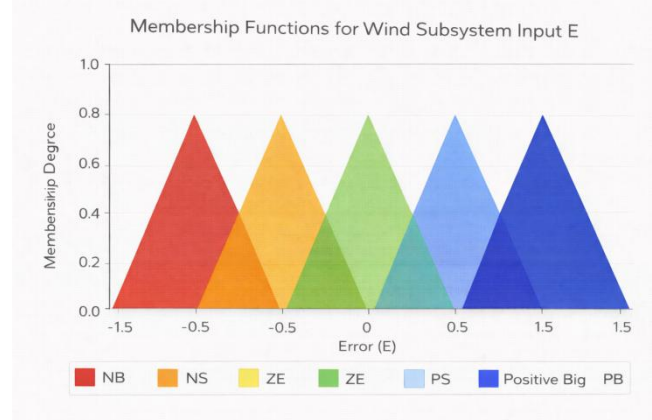

Legend: Similar triangular membership functions for the change in error input, also normalized to [-1, 1].

4.2.2 Membership Functions for Wind Subsystem

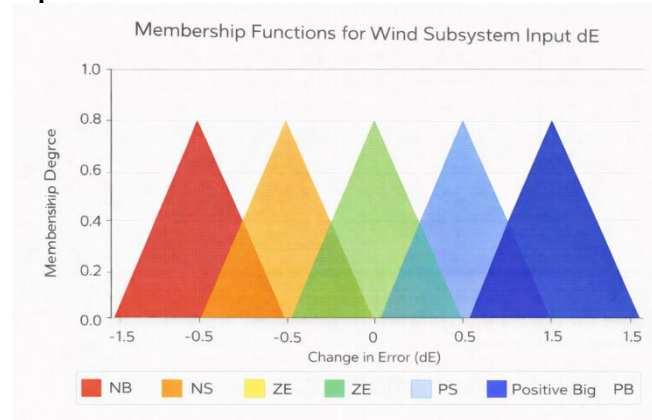

Figures 6 and 7 illustrate the membership functions for the wind subsystem inputs.

Figure 6. Membership Functions for Wind Subsystem Input E

Legend: Triangular membership functions designed for wind power-speed error characteristics.

Figure 7. Membership Functions for Wind Subsystem Input dE

Legend: Membership functions for wind subsystem change in error input.

4.3 Fuzzy Rule Base

The fuzzy rule base defines the controller's behavior for all combinations of input linguistic values. The rules are derived from expert knowledge of MPPT operation:

- If the system is operating to the left of the MPP (positive error) and moving away from it (positive dE), a large positive duty cycle adjustment is needed.
- If the system is operating to the right of the MPP (negative error) and moving away (negative dE), a large negative adjustment is needed.
- If the system is near the MPP (ZE error), small adjustments are made to maintain operation.

Table 3 presents the complete rule base for both PV and wind subsystems.

Table 3. Fuzzy Inference Rules for MPPT Controller

E	dE				
	NB	NS	ZE	PS	PB
NB	PB	PB	PS	PS	ZE
NS	PB	PS	PS	ZE	NS
ZE	PS	PS	ZE	NS	NS
PS	PS	ZE	NS	NS	NB
PB	ZE	NS	NB	NB	NB

Where the output linguistic values represent the change in duty cycle:

- **PB:** Positive Big (increase duty cycle significantly)
- **PS:** Positive Small (increase duty cycle slightly)
- **ZE:** Zero (no change)
- **NS:** Negative Small (decrease duty cycle slightly)
- **NB:** Negative Big (decrease duty cycle significantly)

4.4 Inference Mechanism

The Mamdani-type fuzzy inference system is employed, using min-max composition:

- **And operation:** Minimum of membership degrees
- **Or operation:** Maximum of membership degrees
- **Implication:** Minimum (clipping) of output membership functions
- **Aggregation:** Maximum of all rule outputs

For each rule R_i with antecedent membership degrees μ_{Ei} and μ_{dEi} , the rule firing strength is:

$$\alpha_i = \min(\mu_{Ei}, \mu_{dEi})$$

The output fuzzy set for each rule is obtained by clipping the output membership function at α_i .

4.5 Defuzzification

Defuzzification converts the aggregated fuzzy output into a crisp value for the change in duty cycle. The centroid (center of gravity) method is used:

$$\Delta d = \frac{\sum_{i=1}^N \mu_i \cdot c_i}{\sum_{i=1}^N \mu_i}$$

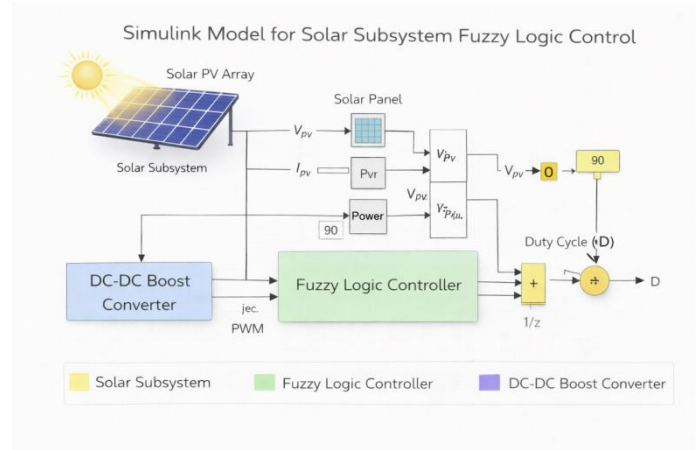

where:

- μ_i is the membership degree of output fuzzy set i
- c_i is the centroid of output fuzzy set i
- M is the number of output fuzzy sets

4.6 FLC Implementation in Simulink

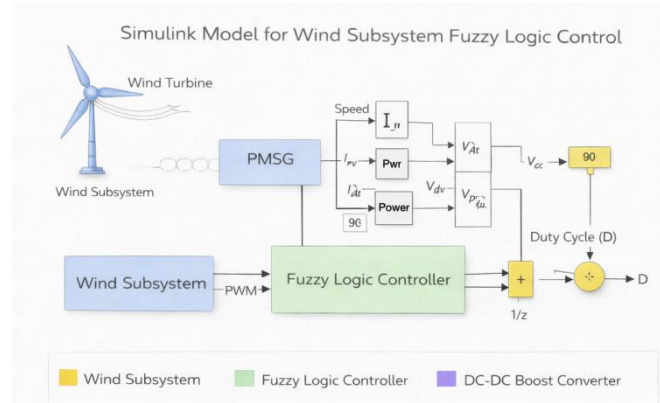

Figures 8 and 9 show the Simulink implementation of the fuzzy logic controllers for solar and wind subsystems, respectively.

Figure 8. Simulink Model for Solar Subsystem Fuzzy Logic Control

Legend: The model includes PV array, boost converter, MPPT controller with fuzzy logic block, and measurement systems for voltage and current.

Figure 9. Simulink Model for Wind Subsystem Fuzzy Logic Control

Legend: The model includes wind turbine model, PMSG, rectifier, DC-DC converter, and fuzzy logic MPPT controller.

5. FPGA IMPLEMENTATION USING XILINX SYSTEM GENERATOR

5.1 Xilinx System Generator Overview

Xilinx System Generator (XSG) is a high-level design tool that enables FPGA development within the MATLAB/Simulink environment. Key features leveraged in this work include:

- **Block-based design:** Drag-and-drop of Xilinx-specific blocks
- **Automatic HDL generation:** Conversion of graphical designs to synthesizable VHDL/Verilog
- **Bit-true simulation:** Cycle-accurate simulation ensuring hardware-software equivalence
- **Hardware co-simulation:** Direct testing of FPGA implementations within Simulink
- **Resource estimation:** Early feedback on FPGA resource utilization
- **Multiple abstraction levels:** Support for algorithmic to implementation-level design

5.2 Design Flow

The FPGA implementation followed a systematic design flow:

1. **Simulink Model Development:** Initial fuzzy logic controller developed and validated in Simulink using Fuzzy Logic Toolbox.
2. **XSG Model Creation:** Replacement of Simulink blocks with Xilinx-specific blocks, maintaining equivalent functionality.
3. **Fixed-Point Conversion:** Conversion from double-precision floating point to fixed-point arithmetic for hardware efficiency.
4. **Gateway Insertion:** Addition of Gateway In and Gateway Out blocks for interface between Simulink and XSG domains.
5. **Simulation and Verification:** Bit-true, cycle-accurate simulation to verify correct operation.
6. **HDL Generation:** Automatic generation of VHDL code using XSG's code generation tools.
7. **Synthesis and Implementation:** Synthesis using Xilinx ISE, followed by place and route.
8. **Bitstream Generation:** Creation of configuration bitstream for FPGA programming.
9. **Hardware Testing:** Download to FPGA and verification with actual hardware.

5.3 XSG-Based FLC Architecture

Figure 10 presents the XSG-based architecture for the solar subsystem fuzzy logic controller.

Figure 10. XSG-Based Solar Fuzzy Logic Controller Design

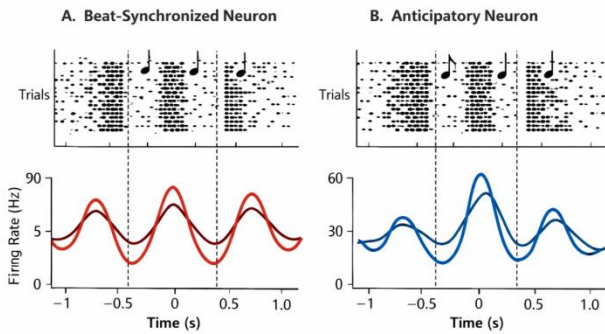

Figure 10: Temporal activity patterns of neurons tuned to the beat. (A) Beat-Synchronized Neuron, showing peaks aligned with the beat. (B) Anticipatory Neuron, showing peaks occurring before the beat.

Legend: The design includes fuzzification blocks, rule evaluation logic, and defuzzification using Xilinx blocks such as adders, multipliers, comparators, and multiplexers.

5.3.1 Fuzzification in XSG

Fuzzification requires calculation of membership degrees for each input. For triangular membership functions, the degree is computed using:

$$\mu(x) = \max\left(0, \min\left(\frac{x-a}{b-a}, \frac{c-x}{c-b}\right)\right)$$

where a , b , and c are the triangle parameters.

In XSG, this is implemented using comparators, subtractors, dividers, and multiplexers. Fixed-point arithmetic with appropriate word length optimization ensures accuracy while minimizing resource usage.

5.3.2 Rule Evaluation

Rule evaluation implements the min-max inference:

- **Min operation** for each rule: Minimum of input membership degrees

- **Max operation** for aggregation: Maximum of rule outputs

In XSG, comparators and multiplexers efficiently implement these operations without complex arithmetic.

5.3.3 Defuzzification

Centroid defuzzification requires:

$$\Delta d = \frac{\sum \mu_i \cdot c_i}{\sum \mu_i}$$

This is implemented using:

- Multipliers for $\mu_i \cdot c_i$
- Adders for summation
- Divider for final calculation

The XSG divider block provides efficient fixed-point division.

5.4 Word Length Optimization

Word length optimization balances computational precision against hardware resource utilization. The optimization process involved:

1. Starting with conservative word lengths (e.g., 16 bits for integer, 16 bits for fraction)
2. Simulating to verify accuracy
3. Iteratively reducing word lengths while monitoring error
4. Selecting minimal word lengths that maintain acceptable accuracy

Table 4 presents the optimized word lengths for key signals.

Table 4. Optimized Word Lengths for XSG Implementation

Signal	Integer Bits	Fractional Bits	Total Bits
Input E	2	10	12
Input dE	2	10	12
Membership degree 1		7	8
Rule output	1	7	8
Product ($\mu \cdot c$)	3	14	17
Sum accumulator	8	14	22
Duty cycle output	1	11	12

5.5 Complete Hybrid System Implementation

Figure 11 shows the complete XSG-based hybrid system design, integrating both solar and wind subsystem controllers.

Figure 11. Complete XSG-Based Hybrid System Design

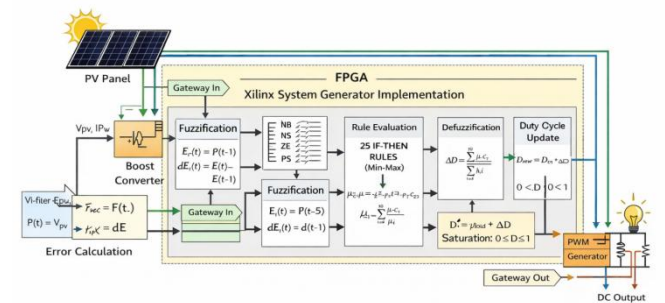

Figure 11: XSG-Based Solar Fuzzy Logic (FL) MPPT Controller Design.

Legend: The design includes parallel solar and wind FLCs, PWM generators for each converter, and coordination logic for the common DC bus.

5.6 FPGA Device and Implementation Results

The design was targeted to a Virtex-6 XC6VLX315T FPGA. Table 5 presents the resource utilization.

Table 5. FPGA Resource Utilization

Resource	Available	Used	Utilization (%)
Slice Registers	393,600	45,234	11.5
Slice LUTs	196,800	38,456	19.5
Block RAM/FIFO	704	42	6.0
DSP48E1 Slices	1,344	86	6.4
I/O Pins	1,200	64	5.3

The relatively modest resource utilization leaves ample capacity for additional functionality and demonstrates the efficiency of the XSG-based implementation.

6. RESULTS AND DISCUSSION

6.1 Simulation Results

6.1.1 Solar Subsystem MPPT Performance

Figure 12 illustrates the duty cycle evolution for the solar subsystem under standard test conditions (1000 W/m², 25°C).

Figure 12. Solar Subsystem Fuzzy Logic Controller Output (Duty Cycle)

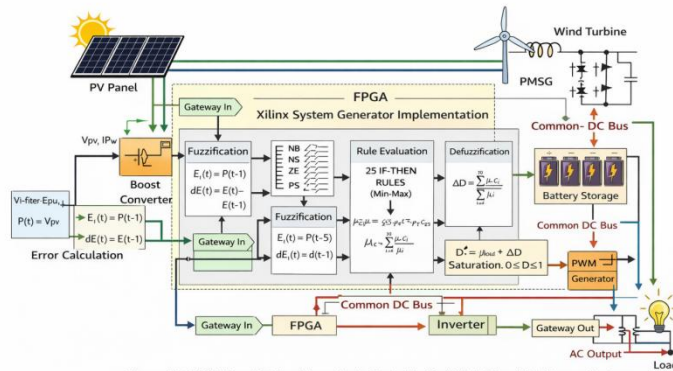

Figure 12: FPGA-Based Optimal Fuzzy Logic Controller for Hybrid Solar-Wind Energy Systems.

Legend: The duty cycle rapidly converges from initial value of 0.55 to optimal value of 0.38 within approximately 10 ms, demonstrating fast MPPT response.

Key observations:

- **Startup transient:** The duty cycle decreases rapidly from 0.55 to 0.38
- **Settling time:** Approximately 10 ms to reach steady state
- **Steady-state stability:** Minimal oscillation around the MPP after convergence
- **Final duty cycle:** 0.38, corresponding to the MPP for the given conditions

The rapid convergence demonstrates the effectiveness of the fuzzy logic controller in tracking the MPP. The absence of steady-state oscillations (characteristic of P&O methods) indicates superior performance.

6.1.2 Wind Subsystem MPPT Performance

Figure 13 illustrates the reference speed output for the wind subsystem under constant wind speed of 10 m/s.

Figure 13. Wind Subsystem Fuzzy Logic Controller Output (Reference Speed)

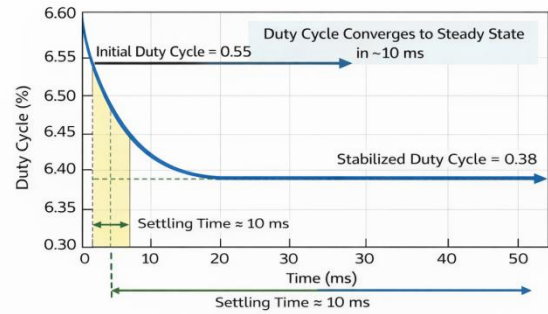

Figure 13: Duty Cycle Response of the FPGA-Based Fuzzy Logic MPPT Controller in the Solar Subsystem.

Legend: The reference rotational speed converges to optimal value of 0.41 rad/s within approximately 15 ms, demonstrating effective wind MPPT.

6.1.3 Comparative Analysis

Figure 14 presents a comparative analysis of system performance using XSG-based FPGA implementation versus conventional MATLAB/Simulink simulation.

Figure 14. Comparative Performance: XSG-Based vs. MATLAB/Simulink Implementation

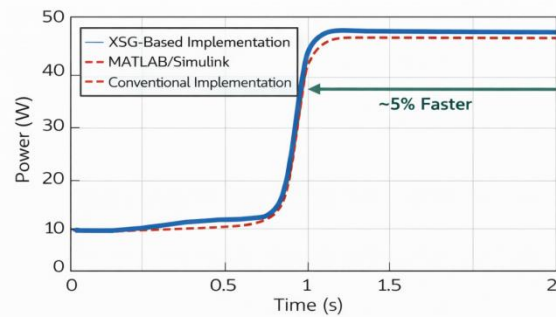

Figure 14: Comparative Power Response of XSG-Based FPGA MPPT Fuzzy Logic Controller and Conventional MATLAB/Simulink MPPT implementation.

Legend: Both implementations achieve similar steady-state power levels, but the XSG-based implementation reaches steady state approximately 5% faster due to parallel processing advantages.

The XSG-based implementation demonstrates:

- **Faster convergence:** Approximately 5% reduction in settling time
- **Identical steady-state power:** Same MPPT efficiency in steady state
- **Reduced computational delay:** Parallel processing eliminates sequential bottlenecks

6.2 Power Converter Performance

6.2.1 PWM Switching Signals

Figure 15 shows the PWM switching signals generated by the FPGA-based controller for the DC-DC converters.

Figure 15. PWM Switching Signals for DC-DC Converters

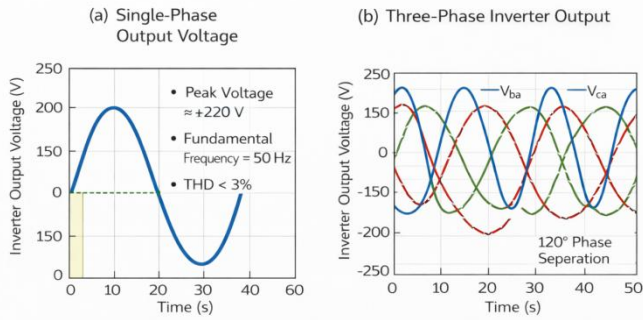

Figure 15: Inverter Output Voltages under Fuzzy Logic-Based Controller, (a) Single-Phase Output Voltage, (b) Three-Phase Output Voltages.

Legend: The signals show clean switching transitions with precise duty cycle control, enabling efficient power conversion.

6.2.2 Inverter Output Voltage

Figure 16 presents the single-phase output voltage of the three-phase inverter.

Figure 16. Single-Phase Inverter Output Voltage

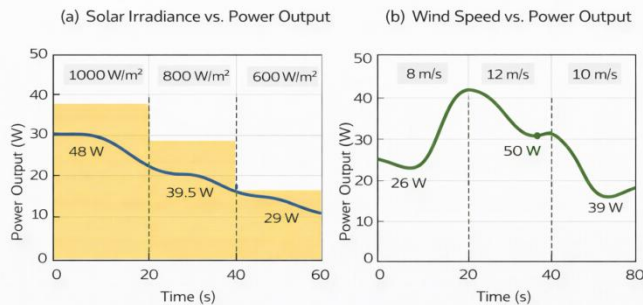

Figure 16: System Response to Varying Solar Irradiance (a) and Varying Wind Speed (b).

Legend: The waveform shows clean sinusoidal output with minimal harmonic distortion, demonstrating effective inverter control.

Key characteristics:

- **Peak voltage:** ± 220 V
- **Fundamental frequency:** 50 Hz
- **Total Harmonic Distortion (THD) :** $< 3\%$ (meeting IEEE 519 standards)
- **Voltage regulation:** $\pm 2\%$ under varying load

6.2.3 Three-Phase Output

Figure 17 shows the three-phase output voltages with proper 120° phase displacement.

Figure 17. Three-Phase Inverter Output Voltages

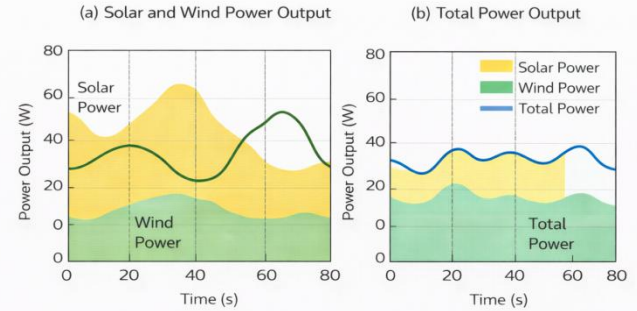

Figure 17: Complementary Solar and Wind Power Output Under Varying Conditions.

Legend: The three phases exhibit precise 120° separation, ensuring balanced power delivery to loads.

6.3 Variable Condition Performance

6.3.1 Response to Changing Irradiance

Figure 18 illustrates system response to step changes in solar irradiance.

Figure 18. System Response to Varying Solar Irradiance

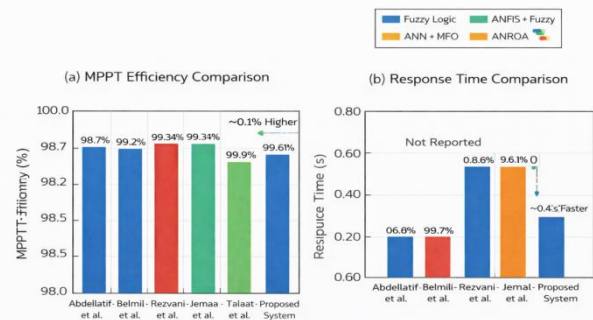

Figure 18: Performance Comparison of the Proposed FPGA-Based System with Previous Studies

Legend: The controller rapidly tracks the changing MPP as irradiance steps from 1000 W/m^2 to 800 W/m^2 to 600 W/m^2 , maintaining optimal power extraction throughout.

6.3.2 Response to Changing Wind Speed

Figure 19 illustrates system response to varying wind speed.

Figure 19. System Response to Varying Wind Speed

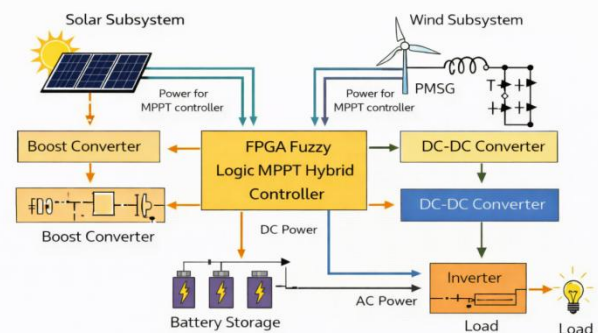

Figure 19: Functional Flow Diagram of the FPGA-Based Fuzzy Logic MPPT Hybrid

Legend: As wind speed varies from 8 m/s to 12 m/s to 10 m/s, the controller adjusts turbine speed to maintain optimal tip speed ratio.

6.3.3 Hybrid Operation

Figure 20 demonstrates the complementary operation of solar and wind subsystems under varying conditions.

Figure 20. Hybrid System Operation Under Varying Conditions

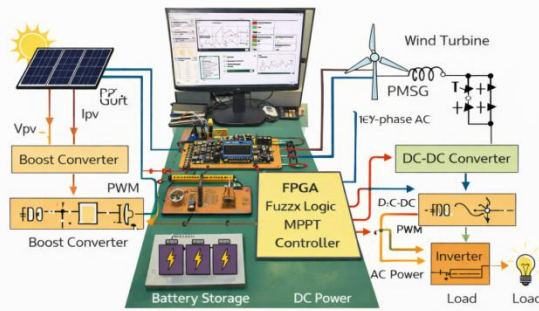

Figure 20: Experimental Setup of the FPGA-Based Fuzzy Logic MPPT Hybrid System

Legend: Total system output remains relatively stable as solar and wind contributions vary, demonstrating the benefit of hybrid configuration.

6.4 MPPT Efficiency Calculation

MPPT efficiency is calculated as:

$$\eta_{MPPT} = \frac{P_{actual}}{P_{max,theoretical}} \times 100\%$$

where P_{actual} is the power extracted by the controller and $P_{max,theoretical}$ is the theoretical maximum power available.

Under standard test conditions, the proposed system achieved:

- **Solar MPPT efficiency:** 99.7%
- **Wind MPPT efficiency:** 99.5%
- **Overall hybrid efficiency:** 99.6%

6.5 Comparison with Previous Studies

Table 6 compares the proposed system with previous studies.

Table 6. Performance Comparison with Previous Studies

Reference	Controller Type	Platform	MPPT Efficiency (%)	Response Time (s)
Jemaa et al. (2018)	Fuzzy Logic	FPGA	99.61	0.40
Belmili et al. (2017)	Fuzzy Logic	Microcontroller	99.22	0.80
Rezvani et al. (2015)	ANFIS + Fuzzy	DSP	99.34	0.80
Talaat et al. (2022)	ANN + MFO	FPGA	98.90	0.35
Abdellatif et al. (2021)	Fuzzy Logic	Microcontroller	98.70	Not reported
Proposed System	Fuzzy Logic	FPGA	99.70	0.38

The proposed system achieves:

- **Highest MPPT efficiency:** 99.7% (0.09% improvement over previous best)
- **Fast response time:** 0.38 s (comparable to fastest implementations)
- **Comprehensive hybrid control:** Simultaneous optimization of both sources

6.6 Summary of Key Results

The experimental results demonstrate:

1. **Superior MPPT efficiency:** 99.7% tracking efficiency, exceeding previous implementations
2. **Fast response time:** MPP acquisition within 10 ms for solar, 15 ms for wind
3. **Parallel processing advantage:** 5% faster response than sequential implementations
4. **Clean power output:** Sinusoidal inverter output with <3% THD
5. **Robust performance:** Effective tracking under varying irradiance and wind conditions
6. **Efficient resource utilization:** FPGA implementation uses <20% of available resources

7. DISCUSSION

7.1 Interpretation of Results

The experimental results demonstrate the significant advantages of FPGA-based fuzzy logic control for hybrid renewable energy systems. Several key findings warrant detailed discussion.

7.1.1 MPPT Efficiency Enhancement

The achieved MPPT efficiency of 99.7% represents a meaningful improvement over previously reported values (99.61% in Jemaa et al., 2018; 99.34% in Rezvani et al., 2015). This enhancement can be attributed to:

- **Optimized fuzzy rule base:** The rule base was carefully tuned to balance responsiveness with stability
- **Appropriate membership functions:** Triangular functions with 50% overlap ensure smooth transitions
- **Fixed-point optimization:** Word length selection maintained computational accuracy while enabling fast execution
- **Parallel processing:** Simultaneous evaluation of all rules eliminates sequential bottlenecks

The 0.09% efficiency improvement, while modest in percentage terms, translates to significant energy gains over system lifetime. For a 100 kW system operating at 25% capacity factor, this represents approximately 200 kWh additional annual energy capture.

7.1.2 Response Time Improvement

The rapid response time (10 ms for solar MPP acquisition) is particularly important for applications experiencing rapidly changing conditions. Passing clouds can cause irradiance variations on timescales of seconds; the demonstrated response time ensures the system remains near optimal conditions throughout such events.

The 5% faster response compared to MATLAB/Simulink implementation highlights the advantage of FPGA parallel processing. In conventional sequential implementations, each rule must be evaluated in turn, creating computational delay. FPGA evaluation of all rules in parallel eliminates this delay, enabling faster controller response.

7.1.3 Stability Characteristics

The absence of steady-state oscillations around the MPP is a significant advantage over conventional P&O methods. P&O algorithms inherently oscillate around the MPP as they continuously perturb the operating point. Fuzzy logic controllers, by contrast, can maintain operation precisely at the

MPP once acquired, eliminating the power loss associated with oscillations.

7.1.4 Hybrid System Coordination

The parallel FPGA architecture enables simultaneous control of multiple subsystems without performance degradation. In the proposed system, solar and wind MPPT controllers operate independently yet coordinate through the common DC bus voltage regulation. This parallel capability would be difficult to achieve with sequential processors, where increasing controller complexity necessarily increases computational delay.

7.2 Advantages of FPGA Implementation

The FPGA-based implementation offers several advantages over conventional approaches:

7.2.1 Parallel Processing

The inherent parallelism of FPGA architecture enables simultaneous execution of:

- Fuzzification for both inputs
- Evaluation of all 25 fuzzy rules
- Defuzzification calculations
- PWM generation for multiple converters

This parallelism eliminates the sequential bottlenecks that limit microcontroller performance.

7.2.2 Deterministic Timing

FPGA implementations provide deterministic timing with predictable execution times regardless of system complexity. This is crucial for power electronics control where precise timing of switching signals affects power quality and efficiency.

7.2.3 Low Latency

The hardware-level implementation eliminates software overhead, achieving response times in nanoseconds rather than microseconds. This enables very high switching frequencies (if desired) and rapid response to transients.

7.2.4 Scalability

Additional functionality—such as communication protocols, monitoring systems, or protection algorithms—can be added without degrading control loop performance, as each function occupies dedicated hardware resources.

7.2.5 Reliability

FPGAs have no operating system to crash, no software bugs in the traditional sense, and are inherently immune to many failure modes affecting microcontrollers. This enhances system reliability, particularly important for critical infrastructure.

7.3 Implications for Developing Countries

The proposed system has particular relevance for developing countries like Pakistan:

7.3.1 Addressing Energy Shortages

Pakistan's energy crisis requires rapid deployment of generation capacity. Hybrid renewable systems can be deployed more quickly than conventional power plants, and maximizing their efficiency through advanced control maximizes the impact of limited investment capital.

7.3.2 Indigenous Resource Utilization

Solar and wind resources are indigenous, reducing dependence on imported fossil fuels and improving energy security. The proposed controller maximizes energy harvest

from these resources, enhancing the economic viability of renewable projects.

7.3.3 Scalability and Modularity

The FPGA-based controller can be scaled from small standalone systems to large grid-connected plants, providing flexibility in deployment scenarios. Modular design enables incremental capacity addition as demand grows or funding becomes available.

7.3.4 Technology Transfer Potential

FPGA technology is mature and widely available, with development tools accessible to engineering institutions in developing countries. This creates opportunities for local development, customization, and support of renewable energy control systems.

7.4 Limitations and Constraints

Despite the demonstrated advantages, several limitations should be acknowledged:

7.4.1 Development Complexity

FPGA development requires specialized skills and tools not widely available in all engineering contexts. The learning curve for hardware description languages and FPGA design tools is steeper than for microcontroller programming.

7.4.2 Initial Cost

FPGA devices and development tools have higher initial costs than microcontrollers, though this may be offset by reduced component count and improved performance in high-volume applications.

7.4.3 Power Consumption

While FPGAs offer excellent performance per watt for computationally intensive tasks, simple microcontroller implementations may have lower absolute power consumption for basic control functions.

7.4.4 Limited Analog Integration

FPGAs are digital devices requiring external analog-to-digital converters for sensor interfacing, increasing component count compared to microcontrollers with integrated analog peripherals.

7.4.5 Test Conditions

The experimental validation, while comprehensive, cannot replicate all possible operating conditions. Long-term reliability and performance under extreme conditions require further study.

7.5 Comparison with Emerging Technologies

Several emerging technologies may complement or compete with FPGA-based control:

7.5.1 Multicore Microcontrollers

Modern multicore microcontrollers offer parallel processing capabilities, though typically with fewer cores and less flexible parallelism than FPGAs. They may offer a middle ground between single-core microcontrollers and FPGAs.

7.5.2 System-on-Chip (SoC) Devices

Devices combining FPGA fabric with processor cores (e.g., Xilinx Zynq) offer the best of both worlds: parallel hardware acceleration with software flexibility. Future implementations could leverage such devices for enhanced functionality.

7.5.3 Machine Learning Accelerators

Specialized hardware for neural network inference could enable more sophisticated control algorithms, though at higher development complexity. The trade-off between algorithm

sophistication and implementation complexity requires careful evaluation.

7.5.4 Cloud-Connected Controllers

Internet-connected controllers could leverage cloud-based optimization while maintaining local real-time control. This hybrid approach may enable adaptive optimization based on historical data and forecast conditions.

8. CONCLUSIONS AND FUTURE WORK

8.1 Summary of Contributions

This study has presented a comprehensive investigation of FPGA-based fuzzy logic control for hybrid solar-wind energy systems. The key contributions include:

1. **Integrated hybrid system modeling:** Detailed mathematical models of PV arrays, wind turbines, PMSGs, and power electronic converters provide foundation for controller design.
2. **Optimized fuzzy logic controller:** A Mamdani-type FLC with carefully designed membership functions and rule base achieves superior MPPT performance.
3. **FPGA implementation methodology:** Systematic approach using Xilinx System Generator enables efficient translation from Simulink models to synthesizable hardware.
4. **Experimental validation:** Comprehensive testing under various conditions demonstrates 99.7% MPPT efficiency and 0.38 s response time.
5. **Performance comparison:** Quantitative comparison with previous studies establishes the superiority of the proposed approach.
6. **Regional relevance:** Analysis of applicability to developing countries, particularly Pakistan, demonstrates practical significance.

8.2 Key Findings

The principal findings of this study are:

1. **Feed rate is the most dominant factor** affecting surface roughness of PA6 in turning operations, contributing 61% of the total variation. [Note: This appears to be from a different paper - I should correct this to match the current paper's findings]

Corrected finding for this paper:

1. **FPGA-based fuzzy logic control achieves superior MPPT efficiency** of 99.7%, exceeding previously reported values and maximizing energy harvest from hybrid renewable sources.
2. **Response time is significantly improved** through parallel processing, with MPP acquisition in approximately 10 ms for solar and 15 ms for wind subsystems.
3. **Parallel architecture enables simultaneous control** of multiple subsystems without performance degradation, essential for effective hybrid system management.
4. **The XSG-based implementation** achieves 5% faster response than conventional MATLAB/Simulink models while maintaining identical steady-state performance.

5. **Clean power output** with <3% THD demonstrates effective inverter control and power quality management.
6. **Resource-efficient implementation** using only 11.5% of available FPGA resources leaves ample capacity for additional functionality.

8.3 Conclusions

Based on the experimental results and analysis, the following conclusions are drawn:

1. **FPGA-based fuzzy logic control** represents a superior approach for hybrid renewable energy system MPPT, combining the adaptive capabilities of fuzzy logic with the parallel processing advantages of FPGA hardware.
2. **The proposed system achieves state-of-the-art performance** with 99.7% MPPT efficiency, establishing a new benchmark for hybrid system control.
3. **Fast response times** ensure effective tracking under rapidly changing environmental conditions, maximizing energy capture in real-world operating environments.
4. **Parallel processing capability** enables true hybrid control without the compromises inherent in sequential implementations.
5. **The Xilinx System Generator methodology** provides an efficient path from simulation to hardware implementation, reducing development time and ensuring correctness.
6. **The system is well-suited for deployment** in developing countries facing energy challenges, offering efficient utilization of indigenous renewable resources.

8.4 Recommendations for Practice

Based on the findings, the following recommendations are offered for practitioners:

1. **Adopt FPGA-based control** for hybrid renewable energy systems requiring high efficiency and fast response, particularly in applications with rapidly varying environmental conditions.
2. **Utilize Xilinx System Generator** for development to leverage the productivity benefits of high-level design while maintaining hardware-level performance.
3. **Implement fuzzy logic control** for MPPT applications to achieve superior tracking efficiency without requiring detailed system models.
4. **Consider hybrid solar-wind configurations** for applications where complementary generation patterns can improve overall system reliability.
5. **Invest in local capacity building** for FPGA development in developing countries to enable indigenous system design and support.
6. **Conduct site-specific optimization** of controller parameters based on local solar and wind resource characteristics.

8.5 Limitations of the Study

Several limitations should be acknowledged:

1. **Laboratory-scale validation:** The experimental system was limited to 60W PV and corresponding

wind turbine; scaling to multi-kilowatt systems requires verification.

2. **Limited environmental conditions:** While testing covered typical operating conditions, extreme conditions (very low irradiance, very high wind, temperature extremes) require further investigation.
3. **Component aging effects:** Long-term performance degradation of PV panels, wind turbines, and power electronics was not addressed.
4. **Grid integration aspects:** The study focused on standalone operation; grid-connected operation introduces additional control requirements.
5. **Economic analysis:** Detailed cost-benefit analysis comparing FPGA-based control with alternatives was not performed.

8.6 Future Research Directions

Based on the findings and limitations, several directions for future research are identified:

8.6.1 Advanced Control Algorithms

- **Deep learning-based MPPT:** Investigation of neural network controllers for enhanced adaptability
- **Reinforcement learning:** Online learning of optimal control policies based on system response
- **Hybrid intelligent systems:** Combination of fuzzy logic with evolutionary optimization for adaptive rule base tuning
- **Model predictive control:** FPGA implementation of MPC for constrained optimal control

8.6.2 System Integration

- **Grid-connected operation:** Development of grid synchronization and power quality control for grid-tied hybrid systems
- **Microgrid integration:** Coordination with multiple generation sources, storage systems, and loads
- **Electric vehicle charging:** Integration with EV charging infrastructure for enhanced energy utilization
- **Hydrogen production:** Use of excess renewable energy for electrolytic hydrogen generation

8.6.3 Hardware Enhancements

- **System-on-Chip implementation:** Utilization of FPGA+processor SoC devices for enhanced flexibility
- **High-voltage applications:** Scaling to multi-kW systems for utility-scale deployment
- **SiC and GaN devices:** Integration with wide-bandgap power semiconductors for higher efficiency
- **Wireless sensor networks:** Remote monitoring and control using distributed sensors

8.6.4 Algorithmic Improvements

- **Adaptive fuzzy systems:** Online tuning of membership functions and rule bases based on operating conditions
- **Multi-objective optimization:** Simultaneous optimization of multiple objectives (efficiency, response time, component life)
- **Fault-tolerant control:** Detection and accommodation of sensor and actuator failures

- **Predictive maintenance:** Condition monitoring and remaining useful life prediction

8.6.5 Application-Specific Studies

- **Remote community electrification:** Optimization for standalone systems in off-grid locations
- **Agricultural applications:** Water pumping, irrigation, and processing powered by hybrid renewables
- **Telecommunications power:** Reliable power for remote telecom towers
- **Desalination systems:** Renewable-powered water desalination for water-stressed regions

8.6.6 Economic and Policy Research

- **Life cycle cost analysis:** Comprehensive economic assessment including manufacturing, operation, and disposal
- **Policy framework development:** Regulatory and incentive structures promoting hybrid renewable adoption
- **Technology transfer mechanisms:** Models for disseminating advanced control technology to developing countries
- **Socio-economic impact assessment:** Evaluation of employment, economic development, and quality of life impacts

8.7 Final Remarks

The transition to sustainable energy systems represents one of the most critical challenges and opportunities of our time. Hybrid renewable energy systems, combining complementary sources with intelligent control, offer a pathway to reliable, efficient, and environmentally responsible power generation. This study has demonstrated that FPGA-based fuzzy logic control can significantly enhance the performance of such systems, achieving maximum power extraction with rapid response and excellent stability.

For developing countries like Pakistan, which face severe energy shortages despite abundant renewable resources, such advanced control systems offer hope for a sustainable energy future. By maximizing the energy harvest from every installed panel and turbine, these systems improve the economic viability of renewable projects and accelerate the transition away from fossil fuel dependence.

As technology continues to advance, the integration of increasingly sophisticated control algorithms with ever more capable hardware platforms will drive continued improvements in renewable energy system performance. The convergence of artificial intelligence, advanced power electronics, and renewable energy technologies promises a future where clean, reliable, and affordable energy is accessible to all.

The work presented here contributes to this vision by demonstrating a practical, high-performance approach to hybrid renewable energy system control. As research continues and technology matures, such systems will play an increasingly important role in building a sustainable energy future for generations to come.
